## USER PROGRAMS DIRECTORY:

The following is a suggested format for the directory:

```
Name of Program
Minimum Memory
Language(I for Integer Basic
                    AT for Applesoft on Tape
                            AR for Applesoft on ROM
E AD for Applesoft Disk -assumes use of disk I/O
    M for Machine Language- i.e NO Basic
```

output -
lights, Heuristics Language hardware. etc

Brief description of what the purpose of the software is Author'a name Date
$G$ for game
$B$ for Business
$I$ for Instructional (Computer aided instruction etc)
U for Utility eg. Create Shape
C for Compilers, Interpreters, Assemblers
S for System (Monitors, HIRES subs, etc)
M for Mathematical(Matrix inversion etc)
H for Home Economics( Checkbook etc)
P for Process Control

USER'S GROUP MEITING- August 9 th 1978
Following matters were agreed to by the majority:

1. Meetings will be held at $7: 30 \mathrm{pm}$ on the and Weds of each month
2. Place of meeting will be Computerland Store, Morgan Circle S, Bloomington. If the size of the group gets large, an alternate meeting place will have: to be found.
3. Users' group will not have any elected officers. One person will act as chairman of each meeting. The chairman will be selected by the group. Dan Buckler has been asked to chair the first few meetings.
4. Users' meeting will be kept as short as possible so that users mayhave time following meeting to discourse with other users.
5. An Agenda will be prepared for each meeting.
6. A Newsletter will be published. Frequency of newsletter will depend onavailat ility of contributions of news. Cost of printing newsletter will be born by Computerland Store in exchange for right to publish advertisements relating to Apple II or Apple II compatible products. Newslet ter will not be mailed to users but will be available for pickup at user meetings. However some newsletter copies will be made available for distrmbution to other User groups in the USA. How such mailing costs will be financed has not been determined.

Newsletter will be handled by Dan Buchler. However helpers and contributory are solicited.
7. Computerland will maintain a directory of programs written by Users. This directory will probably be computerized on an Apple with Apple Disk.

## USERS GROUP MEETING (CONTINUED FREM PREVIOUS PAGE)

8. Because of the time required to reproduce large quantities of proyram tapes, Apple IIs in the Computerland store will not in generai be available for copying of programs. It was suggested that, copying of programs be handled by the individuals who provide those programs. It was pointed out that, Apple provided programs are copyrighted and mat not be reproduced at the store without payment of the program price.
9. Initially there will not be a USERS group membership fee. However it may be necessary to charge such fees at a later date to cover
expenses for such things as meeting room, mailing, etc.
10. It was suggested that new additions to the USERS library be listed in the Newsletter
11. Computerland premises must be vacated by l0pm off the night of the User meetings.

Page 3 of 11

## HIGH FESOLUTION COLOR

Anyone who writes programs utilizing the High Resolution Capability should understand the way in which the High Resolution(HIRES) mode works with resprct to color. However, if you are using a B\&W TV or monitor, set color equal to white and skip the rest of this section.

In the HIRES mode, 230 discrete dots may be selectively displayed on each horizontal ine of the TV. There are 160 or 192 ines available depending on the mode selected. Number the dots 0 through 279 (the X-coordinate). It is a fcat that the ODD dots will be selected and only the ODD dumbered dots, if the first of the two available complimentary colors is specified as the the high resolution color. Converesely, if the color specified is the second of the two available colors, only the EVEN DOTS will be displayed. Looking at it another way, if only the ODD numbered dots are selected, the color of those dots will be that of the first of the two complimentary colors. Or, if only EVEN numbered dots are slected, the color will be the second of the two available complimentary colors. If two consecutive(in X direction) dots are displayed, the effect will be white. To a lesser extent, a green ( $\quad$ (he odd numbered dot color) dot on one line diagonally opposite a violet(the even numbered dot color) in the next line will together appear white. The available colors are

| DOTS | COLOR | $\begin{aligned} & \text { APPLESOFT II } \\ & \text { HCOLOR } \end{aligned}$ | HIRES SUBROUTINE COLOR |
| :---: | :---: | :---: | :---: |
| ODD numbered | Green ${ }^{*}$ | 1,5 | 85(\$55) |
| EVEN numbered | Violet * | 2,6 | 170(\$AA) |

[^0]| GV |  | White |
| :---: | :---: | :---: |
| -• | equals | -• |

## ILIUSTRATION OF HIRES DOT COLORING

Now, what does Apple mean when they say'set the high resolution color' ? In computer language the color is a 'mask'. For color = green Applesoft II HCOLOR = I, HIRES Subroutine color = \$55, the ${ }^{1}$ mask ${ }^{i}$ simply prevents Violet, EVEN numbered dots, from being set. For example in Applesoft II

$$
\begin{aligned}
& 10 \text { HCOLOR }=1 \\
& 20 \text { HPLOT } 0, \mathrm{Y} \text { TO } 279, \mathrm{Y}
\end{aligned}
$$

will cause a horizontal line to be plotted, with the EVEN numbered $X$ -coordinate dots, or violet dots turned off. Another Example:

$$
\begin{aligned}
& 10 \mathrm{X}=11 \\
& 20 \text { HCŌLOR }=1 \\
& 30 \text { HPLOT X,O TO } \mathrm{X}, 159
\end{aligned}
$$

will plot a vertical line at X-coordinate $=11$, which is an ODD numbered dot and therefore Green. Since HCOLOR $=1$, means GREEN, there is no PAGE 4 Of II

HIGH RESOLUTION COLOR( continued, page 2)
conflict. THE LINE WILL BE GREEN . However in the above example, if

$$
10 x=12
$$

and HCOLOR remains set to 1 , the vertical line consists only of EVEN numbered X -coordinate dots, which are :- Viol申t. RESULT- NO VISIBLE LINE! In fact, for vertical lines, green lines can only be plottted for odd values of $X$. Or Green lines can be plotted even when HCOIOR $=3$ (White).

When working directly with the HIRES subroutines, the color is the mask itself. To understand that point, read HIRES Display:. (below).

When using the HIRES subroutine SHAPE, the 'mask' will mask all even dots if set to $\$ 55$, and all odd dots if set to $\mathbb{Z A A}$. For this reason it is difficult to construct a SHAPE in color. If one succeeds in constructing a SHAPEof one color (either all EVEN or all ODD dots), it must be displayed at an even address ( $X$ value) to retain the original color. In practice it is easier to confine shapes to all White (Mask of \$FF)

Applesoft II nominally offers a HIRES Color set of HCOLOR from O through 7. HCOLOR values of 5 and 6 are described as'depending on TV'. In this writer's experrience, all TVs will give same color for 2 and 5 , and for 3 and 6. The effect of using an HCOLOR value of 5 or 6 is to cause the high order bit 7 of the Apple LI byte(s) in the display area which contain the dot(s) to be set of (Bit 7 equals I). See below for more information on byte structures in display area.

## HIRES DISPLAY

A certain fundamental understanding of the Hihg Resolution (HIRES) Display capability is useful in programming graphics on the Apple II in Applesoft II or with the HIRES Subroutines.

2 HIRES modes of operation are available:-
HIRES GRAPHICS MODE
MIXED HIRES GRAPHICS MODE
In the HIRES Graphics Mode, the screen is divided into 280 horizontal by 192 vertical dots. NO TEXT can be displayed except by use of characters generated in software and displayed as HIRES patterns or SHAPES.

In the MIXED HIRES GRAPHICS MODE, the upper portion of the screen is divided into 280 horizonđal by 160 vertical dots. The lower portion of the screen is available for 4 lines of 40 characters of standard text (PRINT statements)

Low Resolution 16 color graphics may not be used in conjunction with either HIRES mode.

2 colors areavailable in HIRES Modes as described in the section on HIRES color. The setting and clearing of the above HIRES modes is described in the Applesoft II manuals and in the Apple II manual.

Page 5 of 11

## HIRES DISPLAY (Continued)

The Information displayed on the screen is derived from Apple II memory. This memory is called a'page '. 2 different pages may be defined.

PAGE 1 uses 2nd 8 k of memory \$2000 to \$3FFF
PAGE 2 uses 3 rd 8 K of memory $\$ 4000$ to $\$ 5 \mathrm{FFF}$
Page 2 may be invoked with references to $\$ \mathrm{CO} 54$ and $\$ \mathrm{CO} 55$. See page 30 of Apple II Reference Manual.

Each dot on the screen is represented by one bit in the selected page - of memory. If the bit is on, that is a one, the dot is on. See HIRES COLOR above for discussion on color of dot. In each byte in the selected page of memory, only the lower 7 bits are used to turn dots on and off. That is bits 0 through 6 . Bit 7 is used the select the alternate HIRES Color (Applesoft II colors (HCOLOR) 4 through 7). Since there are 280 dots in a line, $280 \div 7$ which is 40 bytes are needed per line. These bytes are contiguous for any particular line. See figure below

lst 3 bytes in a 40 byte set which displays one horizontal line in HIRES GRAPHICS
Note the Bit 7 is used for the alternate HCOLOR selection(See HIRES Color)
The 40 words (bytes) which display one horizontal line of the 160 or 192 available are not sequential in the memory page with respect to the $Y$ coordinate value. Apple adopted a nifty addressing scheme which was easily implemented in the display hardware logic. This scheme works as folows:

Y, the Y coordinate lies between 0 and 159 (or 191) and is represented pictorially as an 8 bit number-

$$
H_{7} H_{6} M_{5} M_{4} M_{3} L_{2} L_{7} L_{0}
$$

$\mathrm{L}, \mathrm{M}$ and H are bits with the $\mathrm{L}, \mathrm{M}$ and H standing for Low order( 3 bits). Medium order ( 3 bits) and High order ( 2 bits). Bit representation is standard 6502 nomenclature. In assembling the page address of the first word of the 40 that represent a horizontal line, the word(byte) with the $X$ cordinates 0 through 6 in it, the resultant address looks like

$$
\begin{aligned}
P_{1} P_{0} & \text { is } 01 \text { for page } 1 \text {, } 10 \text { for page },
\end{aligned}
$$

Note that the 2 high order bits $H_{6} H_{7}$ appear twice each. This is the nifty scheme which makes the address go up in jumps of 40 . The actual addresses corresponding to different values of $Y$ can be found in the table on the next page. 40 bytes X 192 lines results in 7680 bytes of the 8192 available in a page. Those 512 unused bytes(warning they are

## HIRES DISPLAY (Continued)

set to zero by the HIRES clear routine) are spread through the page in 8 byte blocks, These are shown by dashes in table below.

TABLE SHOWING RELATIONSHIP OF PAGE 1 HIRES 40 BYTE DISPLAY LINE ADDRESS TO Y-COORDINATE VALUE

Only lst 72 values of $Y$ are detailed. The small table below details $Y$ from 3 to 8. A study of these two tables will

Page 7 of 11

High Eesolution Operating Subroutines:
(This page replaces page 47 in Apple II Ref Manual)
Those routines which require the passing of parameters have two entry point
With one, parameters are passed via specified memory locations. We will cald
this type ' $m$ ' (for memory). This entry point is always used from BASIC
and may be optionally used from machine lanquage programs. It causes the $X$ register to be saved and then loads the $A, X \& Y$ registers from the appropriate memory locations. On exit the $X$ register is restored.

The other entry point provides for the parameters to be passed via the 6502 registers without storing that information in the specified memory locations. This entry point may optionally be used from machine lanquage p rograms. It may not be used for calls from BASIC. We will call this entry point type 'r' for register :
INIT Initializes High-Resolution Graphics mode.
From basic: CALL 3972 (or CALL-12288)
From machine language: JSR \$C円ø (or JSR $\$ D \rho \rho g)$

This subroutine sets High-Resolution Graphics mode with a $288 \times 169$ matrix of dots in the top portion of the screen and four lines of text in the bottom portion of the screen. INIT also clears the screen.

## CLEAR Clears the screen.

From basic: CALL 3086 (or CALL -12274)
From machine language: JSR \$CfE (OP JSR \$DODE)

This subroutine clears the ligh-Resolution screen without resetting the High-Resolution Graphics mode.

PLOT Plots a point on the screen.
From BASIC: CALL 3780 (or CALL - 11580)
From machine lanquage (type r): JSR \$c7C (or JSR \$807C)
This subroutine plots a single point on the screen. The $x \& Y$ co-ordinates of the point are passed in location 800,801 and 802 from BASIC ( $\$ 320, \$ 321$ \& $\$ 322$ from type $m$ ), or in the $A, X$ and $Y$ registers for type $r$ machine language calls. The $Y(v e r t i c a l)$ coordinate can be from 0

Page 8 of 17

PLOT (Continued)
top of screen to 159 (bottom of screen) and is passed in location 802 ( $\$ 322$ ) or the $Y$ register; but the $X$ (horizontal) coordinate can range from 0 (left side of screen) to 279 (right side of screen) and must be split between locations 800 ( $\$ 320$ ), X MOD 256 in BASIC or the A-register in $r$ type calls and location 801 ( $\$ 321$ ), $X / 256$ or $X \geqslant 256$ in BASIC, or the $X$ register for $r$ type calls. Note the low order byte is in the first of the $X$ registe
pair following standard 6502 practice.
The color of the point to be plotted must be set in location 812 (\$320)
See discusion on HIRES colors.
POSN Positions a point on the screen.
From BASIC: CALL 3761 ( or CALL - 11599 )
From machine language (type r): JSR \$C26 (or JSR \$DO26)
This subroutine does all the calculations for a plot, but does not plot a point(it leaves the creen unzhanged). This is useful when used in conjunction with IINE or SHAPE (described later). To use the subroutine, set up the $X$ and $Y$ coordinates just the same as for PLOT. The color in LINE Draw a line on the screen.
From BASIC: CALL 3786 (or CALL -11574)
From machine language: (type r): JSR \$C95 (or JSR \$D095)
(type m): JSR \$ECA
This subroutine draws a line from the last point PDOTed or POSN'ed to the point specified. One endpoint is the last point PLOTted or POSN'ed; the other endpoint is passed in the same manner as for a PLOT or POSN. The color of the line is set in location 812(\$32C). Note, as described in section on HIRES COLOR, only points corresponding to the selected color will be plotted. Therefore, unless white ' $\$ 255^{\prime}$ is used parts or even becomes the base endpoint for the next line drawn drawn, the new endpoint SHAPE Draws a predefined 'shape' on the screen From BASIC : CALL 3805 (or CAL工 -11555)
From machine language (type r): JSR $\begin{gathered}\text { \#DBC } \\ \text { (typ } \mathrm{e} m \text { ) }: J S R \\ \$ E D D\end{gathered}$ (or JSR \$DIBC)
This subroutine draws a predefined shape on the screen at the point previously PLOTted or POSN'ed. It also will start a SHAPE at the en of the last SHAPE drawn. The SHAPE is defined by SHAFE at the endpoint memory. How to create this table of vectors is descibed table of vectors in UTILITY program CREATE SHAFE, taken from the JULY JAUG later or the COMPUTING magazine maybe used to create and save faUG edition of CREATIVE MINI'APP'LES USERS GROUP LIBRARY)

The starting adress of the table of vectors is passed in locations Page 9 of II

## HIGH RESOLUTION GRAPHIC SUBROUTINES (Cont)

(This page replaces page 49 of thw Apple II reference manual)

## SHAPE (Cont)

804 ( $\$ 324$ ) and 805 ( $\$ 325$ ) from BASIC or type m machine language, or 1 n the Y and X registers for type $r$ machine language. The color of the shape should be passed in location 28 (\$1C) (The following has not been absolutely verified, but this writer beleives that since 28 is part of register \#I4 in the SWEET 1616 bit interpreter, which is itelf part of the APPLE II monitor, location 28 gets clobbered by subsequent calls to POSN etc. It therefore must be restored prior to each call to SHAFE) Please also read the discusion on COLOR in HIRES COLOR. Use of colors other than white will almost certainly delete pieces of the shape.

There are two special variables that are used only with the SHAPE routine: the scaling factor and the rotation factor. When the scaling factor is used additional dots are generated under conditions but the routine will not create a solid line or block just because there was a solid block before. The ability to rotate the image depends on the scaing factor because the roation is calculated in a vector form similar to the way in which the vector table was created in the first place. The rotation resolution is limited according to the following table

| Scale Factor |
| :--- |
| 1 |
| 2 |
| 4 |
| 8 |
| 16 |

Available rotations
0,16(90 değrees) , 32, 48
$0,8(45$ degrees $), 16,24,32,40,48$ and 56
$0,4,8,12,16$ etc
$0,2,4,6,8,10,12,14,16,18$ etc
A11 64

The scaling factor determins the relative size multiplication of the shape. Foe example a scale factor of 2 will plot a shape 20 points long if the vector table defines it as 10 points long. When rotation is employed there will be some distortion of the image due to the non linearity of the vertical point spacing relative to the horizontal and because of the vector techniaue used to create rotations, A scaling factor of

## High Resolution Graphic Subroutines

Additional information:
The last sector of the subroutine $F O O$ to $F F F$ contains a table of 8 bit SINE values called the SINTBL.

IfTHETAis the angle in dearees for which the SINE is to be found: then the SINE will be found at ..

$$
\begin{aligned}
& \text { \$FOO }+256 * \text { THETA } / 360 \\
& \text { or } \quad \text { \#FOO }+32 \# \text { THETA } / 45
\end{aligned}
$$

The resulting SINE value is excess 128 ; that is it has $\$ 80$ added to it - It is also multiplied by 128; or, thinking of it in another way, the decimal point precedes thr lst hexidecimal number.

Example in BASIC. Let us say we want to solve the problem:

$$
A=B \quad * \operatorname{SIN}(T H E T A)
$$

This is performed as follows:

| 100 | SINTBL $=3840$ |
| :--- | :--- |
| 200 | $\mathrm{~A}=(\mathrm{PEE} \overline{\bar{K}}(S I N T B L+T H E T A * 32 / 45)-128) * B / 128$ |

In tinis particular example if $B$ is less than 128 , some precision is lost and the expression should be scaled accordingly. Note aiso that the SINTBL covers: 4 quadrants ( 0 to 360 degrees). If THETA could be greater than 360 , it must be modulus 360 i.e THETA MOD 360

Since SINE is negadtive in the 3 rd and 4 th quadrant, the values of SINTBL lie between 0 and $\$ 80$. In the first and 2nd quadrant they lie between $\$ 80$ and $\$ F F$ 。

Another routine FIND is also provided in HIRES at 3667. I have'nt figured that one out yet.

[^0]:    *Adjustment of the color controls(Tint \& Density) can alter these to Yellow/Blue or Red/Blue
