Note: Before going any farther, listen to the mission briefing on the enclosed cassette (if you haven't already done so). If you do not have an audio playback device, read the transcript of the cassette at the back of this dossier.
To: Specially Selected Star Pilots
From: P.L.A.N.E.T.
Re: THE HALLEY PROJECT

By now, you should have listened to (or read the transcript of) the coded transmission from P.L.A.N.E.T. We are pleased that you have accepted the challenge to attempt to qualify for The Halley Project. Pilots, this is no ordinary challenge, but you are not ordinary pilots. No mere neophyte could hope to fulfill these requirements.

The 10 training missions you are about to begin will test even the best of you. If you demonstrate the skill, knowledge, and cunning necessary to succeed, you will be invited to join the final challenge, The Halley Project. It's as simple as that.

Your briefing consists of the classified files listed below. You will find them all in this dossier, your Mission Technical Reference Guide. Read them carefully. They are designed to help you qualify for The Halley Project. These top-secret files and the Flight Instructions Reference Card include basic technical operating instructions for your spaceship and offer some advice for locating and landing on planets. But you will need to summon all your flying skill and knowledge of the Solar System to complete all your training missions.

Following are brief descriptions of each top-secret file:

**Qualification Procedures for The Halley Project** – a quick overview of the training missions and the scope of the project.

**Starting the Missions: Powering Up** – how to get going on your first mission.

**The Control Panel** – describes the equipment on your spaceship control panel and explains how to use this equipment to reach your destinations.
Navigating and Landing – explains how to use the program’s Radar Screen and the Simple Star Map (enclosed with this package) to locate positions of planets and moons; provides step-by-step procedures for landing on planets and moons.

The Halley Project Missions Chart – lets you keep track of the planets and moons you’re directed to land on for each mission.

Intelligence-Gathering Resources – interesting books and articles that can increase your knowledge of space exploration, astronomy, and Halley’s Comet. Some of them may help you solve the clues you are given with each mission.

Debriefing – procedures to help you remain in touch with the Solar System after you complete your missions and return to Earth; includes star-gazing activities.

Transcript of the Mission Briefing – a transcript of the briefing on the enclosed cassette, for those of you who don’t have an audio playback device.

Other Important Documents

Also included in this package are a Flight Instructions Reference Card and a Simple Star Map. Keep them handy; you will probably want to refer to them frequently.

Flight Instructions Reference – a rundown of your equipment’s technical specifications, loading instructions, and some helpful hints on flying.

Simple Star Map – a map of the major constellations, as seen through your spaceship viewing screen. This map will be an invaluable help to you as you navigate in space; without it, you will be merely a cosmic drifter. Note that the Simple Star Map does not include every star visible from the Solar System, but represents the view from your ship.
Qualification Procedures for The Halley Project

You begin your quest to qualify for The Halley Project without rank. To join The Halley Project, you must master 10 ranks, from Raven to Starbird. To advance a rank, you must fly the appropriate course, or mission, between specified bodies of the Solar System, landing on each planet or moon as you are directed.

As you begin each mission, you will be given instructions on the screen. Due to the sensitive nature of this information, you will not have access to specific instructions until you qualify for a specific mission. To further protect the secrecy of the missions, the instructions are often given as clues. You have to figure out where to go. To unravel the clue, you may need to do a little research on your own before you sojourn in the Solar System. For example, you might be told to land on a moon that has an atmosphere. Unless you can determine which moons fit this description and then maneuver yourself there, The Halley Project isn't for you. Note: Due to limitations in microcomputer technology, not all the moons of Jupiter and Saturn could be represented properly in the program. You will not be asked to travel to those moons that have not been included.

Keep in mind that each planet and moon revolves around the sun. Thus, each has a "dark side"—the side that seems invisible because it's facing away from the sun. Do not fear the dark side. Sometimes you may find your landing clearance on that side. See the Navigating and Landing File for additional information. Each mission begins and ends at the secret training installation located on Halley's Comet. Successful completion of a mission moves you to the next rank.

You will be timed, and the four fastest times will be recorded. Those with the fastest times will have the satisfaction of knowing they are the most qualified pilots in the galaxy. However, you don't have to be among the four fastest times to qualify for The Halley Project. Remember, only the best will endure PL.A.N.E.T.'s tests to become part of The Halley Project. You must advance through the ranks in the order listed below.

1. Raven
2. Shrike
3. Vulture
4. Darter
5. Condor
6. Swift
7. Nighthawk
8. Falcon
9. Eagle
10. Starbird
Complete each mission in order. You cannot attempt the Nighthawk's mission, for example, until you have completed all the missions before it. You can redo missions as often as you like to improve your times. Listed below are some challenge times worth flying for:

<table>
<thead>
<tr>
<th>Mission</th>
<th>Time (in minutes and seconds)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Raven</td>
<td>3:00</td>
</tr>
<tr>
<td>2. Shrike</td>
<td>4:30</td>
</tr>
<tr>
<td>3. Vulture</td>
<td>8:00</td>
</tr>
<tr>
<td>4. Darter</td>
<td>9:00</td>
</tr>
<tr>
<td>5. Condor</td>
<td>9:00</td>
</tr>
<tr>
<td>6. Swift</td>
<td>15:00</td>
</tr>
<tr>
<td>7. Nighthawk</td>
<td>10:00</td>
</tr>
<tr>
<td>8. Falcon</td>
<td>15:00</td>
</tr>
<tr>
<td>9. Eagle</td>
<td>20:00</td>
</tr>
<tr>
<td>10. Starbird</td>
<td>20:00</td>
</tr>
</tbody>
</table>

You qualify for The Halley Project by completing the 10 missions listed above. When you finish the Starbird mission, you’ll be given a secret code number. Fill out the RFC (Registration for Certification) included with this dossier. The RFC must arrive at P.L.A.N.E.T. Headquarters by December 31, 1985, if you want P.L.A.N.E.T. to compare your performance with that of other pilots. Give your secret code number and give the name you used during your P.L.A.N.E.T. missions. If those credentials match the ones that P.L.A.N.E.T. secretly assigned you, you will receive official certification that you have qualified to participate in The Halley Project. Information about the most exacting mission of all, The Halley Project itself, will be sent to you at a later date.

**The Final Challenge**

Being accepted as a participant in The Halley Project, the final challenge, is impressive. But the mysterious Halley Project itself also awaits. Hidden within the program is the key to the final challenge, but details won’t be divulged... yet. To learn about The Halley Project's final challenge, complete all 10 missions, and return the enclosed Registration for Certification form. The RFC must arrive at P.L.A.N.E.T. Headquarters by December 31, 1985, if you want P.L.A.N.E.T. to compare your performance with that of other pilots. Then keep your eyes and ears open for the FINAL CHALLENGE. P.L.A.N.E.T. will find you!
Starting the Missions: Powering Up

To get started on your mission, follow these steps:

1. Load the disk according to the directions on the enclosed Flight Instructions Reference Card.

2. After you've read the initial screens, you will see a name roster screen. Use the joystick* to select a blank line. Press the joystick button. Then type in the name you want to use as a pilot and press RETURN.

3. Choose the mission you want to fly by using the joystick to move the asterisk in front of that mission. Press the joystick button. (Remember that you must begin by flying the Raven mission. You can repeat a mission you've already done to improve your time, but you must do the missions in order.)

4. Read the directions on the screen that tell you what your destination is. It will be a planet or moon.

5. Use the Radar Screen and the Simple Star Map to determine where your destination is and how to get there.

6. Navigate your way to and then land on your destination. (See the Navigating and Landing File.) Once you've landed, proceed according to the instructions on the screen. Press B to blast off for your next destination.

*Throughout this manual, the input device is referred to as the joystick. Some versions may use the keyboard, a mouse, or other devices. Please see your Flight Instructions Reference Card for information.
The Control Panel

During each mission, you're seated at the control panel of your spaceship, somewhere in our Solar System. From your Viewing Screen, you see constellations, stars, planets, and moons just as they appear in space. Objects in space are very far away from each other. To help you reach your destinations, your ship is equipped with some special devices.

**Viewing Screen** — You can observe all the space around you through this Viewing Screen. Follow the steps on the Flight Instructions Reference Card to change your field of vision to see different views. It's usually a good idea to come to a complete stop before changing your field of vision.

**Direction Pointer** — This device shows which direction you are moving. For example, when you are moving toward a planet or moon shown on your Viewing Screen, the pointer will be up at the top of the dial. When you are moving away from an object, the pointer will be at the bottom of the dial. Thus, it is possible to be looking at a planet but be moving away from it.

**Planet/Moon Finder** — The marked area in the center of the Viewing Screen is your Planet/Moon Finder. The four marked corners will
light up when a planet or moon comes within range. The Sun is always visible through the Finder.

**Planet/Moon Indicator**—As you approach an object and it becomes clearer, its name and your distance from it will appear here.

**Power Meter**—Your ship has two power levels, low and high. High is best for traveling great distances. It gives the engines more power. Low gives you more control and is helpful when maneuvering for a landing. To select a power level, press L for Low and H for High.

**Speed**—Keep a careful watch on your speed. It is very easy to fly by a planet or moon if you are going too fast. When your speed reaches 250,000 km/s (kilometers per second), you will hear warning sounds. At 300,000 km/s, the speed of light, you jump to Hyperspace. In Hyperspace, you travel at many times the speed of light.

**Timer**—The timer keeps track of the time it takes you to fly each mission. The timer does not run when you are not moving.

---

**Using the Control Panel**

**To move in a direction,** push the joystick in that direction. The longer you hold the joystick in that direction, the faster you will go. (Pilots using something other than a joystick should consult the Flight Instructions Reference Card.)

**To go into Hyperspace,** increase your speed to 300,000 km/s (the speed of light). A warning buzzer will sound when your speed reaches 250,000 km/s to let you know you're approaching Hyperspace. Once in Hyperspace, your distance traveled is reported in millions of kilometers.

**To slow down or stop,** press the space bar. If you are in Hyperspace, pressing the space bar brings you to an immediate stop. If you are traveling at a speed less than 300,000 km/s, each press of the space bar cuts your speed in half.

**To change your field of vision,** hold the joystick button down while you move the joystick to the right or to the left. NOTE: This will not change the direction in which you are moving. You may find it easier to come to a stop first before changing your field of vision.

**To select your power level,** press H for High Power or L for Low Power.
To engage the automatic landing system, press A on the keyboard. You can land only when the Planet/Moon Finder is blinking and beeping. See File #00235THP-4 for more information about landing. **(NOTE: There is no special landing area on Halley's Comet; to return to P.L.A.N.E.T.'s secret installation, simply fly right into the comet.)**

To blast off from a planet or moon, press B on the keyboard.

To see the Radar Screen, press R on the keyboard.

---

**Using The Radar Screen**

Your ship always stays at the center of the screen.

**To zoom in,** push forward on the joystick. When you zoom in, you see an enlarged view of the small region of space near your ship. You may not see all the planets on the screen at the same time.

**To zoom out,** pull back on the joystick. When you zoom out, you see an overview of the whole Solar System.

**To return to the Control Panel,** press R on the keyboard.

For a more detailed explanation of Radar Screen use, see the classified Navigating and Landing File (#00235THP-4).
Navigating and Landing

Space is a big place, and it's easy to get lost. Who knows how many amateur pilots are stranded somewhere in space because they never learned to navigate using their radar and the constellations on the Simple Star Map? Who knows how many are in eternal holding patterns because they never learned landing procedures? Don't let these disasters happen to you.

Navigating

Your Radar Screen and Simple Star Map (included with the program package) are essential instruments for navigating through the Solar System. Use them to help you go from one destination to the next.

Radar—Press R to see the Radar Screen. Step-by-step instructions for navigating by radar follow. Let's assume that you have just started a mission and that your destination is Earth.

1. At the beginning of each mission, a message appears on the screen telling you your destination. The message may specify the destination or it may only give you a clue. If necessary, do some research to decipher a mission clue. In this example, your goal is to find and land on Earth.

As soon as you embark on a mission, you will immediately see a huge white sphere filling the Viewing Screen of your ship. That is Halley's Comet. Your missions always begin at Halley's Comet, and your ship is always moving away from the comet as the mission begins. As you get farther away, the comet will look smaller and smaller. The tail will become visible. Keep moving away from the comet until you are about 500,000 km away. That will give you a good look at it. You'll need to know what it looks like because you will have to return to the secret training installation there many times during your interplanetary travels.
2. Now begin braking your ship. You brake by pressing the space bar. Each time you press the space bar, your speed is cut in half. Try to bring the ship to a complete stop (0 km) when it is, say, 600,000 km away from the comet. Then press R to check the Radar Screen. Find your current position. You will see something like this:
You are always the X in the middle of the circle. Halley’s Comet is the flashing dot that, depending on your position, may or may not be visible. Remember that each mission begins at Halley’s Comet. So, if you go right to the Radar Screen at the beginning of a mission, Halley’s Comet will also be at or near the center of the screen.

**Note:** Each time you use the program, your exact distance from Earth and your orientation may vary. Remember that all the planets and Halley’s Comet are constantly revolving around the sun.

The sun is the largest and brightest dot in the circle. It is truly one of the universe’s hot spots, too hot even for star pilots. That’s one place you don’t want to go. The other dots are the planets. The names of the constellations are located around the outside of the circle. The number at the bottom of the screen indicates the distance, in millions of kilometers, from you to the edge of the circle.

3. Locate your destination planet. In this case, you are looking for Earth. (If your destination is a moon, locate the planet that the moon orbits.) To identify a planet, start from the sun and count out toward the edge of the circle. Earth is the third planet away from the sun. Only Mercury and Venus are closer.

4. If at first you don’t see anything helpful on the Radar Screen, zoom OUT by pulling the joystick backward. Now the screen may look like this:
5. If at first the planets appear tightly bunched on the Radar Screen, zoom IN for a closer look by pushing the joystick forward. Now the screen might look like this:

6. Once you find your destination, pull the joystick back until your destination is on the edge of the circle. For this demonstration, pull the joystick back now until Earth is on the edge of the circle. Check the distance scale on the bottom of the screen. That number (in millions of kilometers) is the planet's distance from you.
Your distance from Earth will vary each time you run the program. For example, when you check the Radar Screen, you might find that Earth is 470 million kilometers away from you in the direction of Scorpio. The next time you use the program and try to go to Earth, you might find that Earth is 370 million kilometers away in the direction of Sagittarius.

**Earth at Edge of Circle on Radar Screen**

7. Notice where your destination is in relation to the constellations shown around the circle. To use the example above, you might find that Earth is 470 million kilometers away in the direction of Scorpio. Once you have lined up Earth with a constellation, look at the Simple Star Map to figure out how to locate that constellation.

**Simple Star Map** The Simple Star Map does not include all the stars visible from our Solar System. What it does represent is your field of vision as seen through the Viewing Screen of your spaceship.

On the Simple Star Map you can see 12 constellations. The stars of these constellations are so far away that, no matter how far you travel in our Solar System, they never appear to move. They are fixed points that can guide you to your destinations. Here's how:

You have already used the Radar Screen to determine how far you are from your destination (in this case, Earth).

1. Find the appropriate constellation on the Star Map. Let's say you are looking for Scorpio.
2. Press R on the keyboard to return from the Radar Screen to the Control Panel. Make sure that you are still at a complete stop, then swivel through your field of vision (see Flight Instructions Reference Card) until you find your constellation on the Viewing Screen. If you are using a joystick, make sure you keep the joystick button down while you swivel. Otherwise, your ship will start accelerating again, perhaps in the wrong direction.

It is often helpful to look for simple, distinct patterns in the stars. If you locate one constellation, you can usually identify those near it.

3. With the constellation fixed in your Viewing Screen, look for your planet. If you are not close enough to the planet, you will not be able to spot it. In this case, Earth is not yet visible because it is too far away. When you are close enough to have the planet in view, it may look like a star. Compare what you see on the Viewing Screen to your Simple Star Map. A “star” that doesn’t appear on the map but that appears in the constellation you are viewing on the screen may well be the planet you seek.

4. Once you spot your goal, you are ready to accelerate toward it and try to land. To find Earth, you will first have to fly toward the constellation until you get close enough to see Earth in your Planet/Moon Finder.
Landing

Landing on a planet or moon takes skill and practice. This is where the true star pilots get to show their stuff. Let's continue to assume for now that you are going to land on Earth.

Using Hyperspace—When Your Destination Is Far Away If you have followed along so far, you have your bearings. You have used your Radar Screen to line up Earth with one of the constellations. You know you are x millions of kilometers away from Earth in the direction of one of the constellations. For example, you might be 470 million kilometers away from Earth in the direction of Scorpio. Through your Viewing Screen, the constellation is visible. You are ready for your flight.

1. Make sure you are at a complete stop. That way you will be certain to follow a straight course once you jump to Hyperspace.

2. Set your power to High by pressing H on the keyboard. Move your ship directly ahead—toward the constellation that you've lined up in your Viewing Screen—by pushing the joystick straight forward. Your ship will begin accelerating.

3. Increase your speed. A warning will sound when you reach 250,000 km/s. When you hit 300,000 km/s you will jump to Hyperspace. In Hyperspace you move quickly, traveling many millions of kilometers per second. The distance you travel in Hyperspace is displayed on your Viewing Screen. Remember that the distance indicated on your Radar Screen is the distance between you and your destination, in this case Earth.
**WARNING:** When traveling in Hyperspace, you will be moving faster than the speed of light. It is very easy to "overshoot" your destination by many millions of kilometers. Take extra caution when traveling at this speed.

4. When you are within 20 to 30 million kilometers of your destination, press the space bar to brake. For example, if you need to go 470 million kilometers, brake when you reach 440 to 450. When you press the space bar, you will come to a screeching halt.

5. If your destination is in sight, you will see the name of the planet or moon and your distance from it displayed on the Planet/Moon Indicator on your Control Panel. If Earth is in view now, keep it inside the Planet/Moon Finder as you approach. To do this, you may have to adjust your direction a bit. Landing will be a little bit like trying to hit a slowly moving target.

   If your destination is not in sight, check the Radar Screen to see how close you have come to your destination. If you still have more than 25 or 30 million km to go, move into Hyperspace again very briefly to get closer. Then go back to the Control Panel and turn your ship around until Earth comes into view.

   If you cannot find Earth, you may have gone too far. Check the Radar Screen to see if you overshot your mark. You may find that Earth is now in the direction of one of the other constellations. If that is true,
you will have to find that constellation in your Viewing Screen, just as you spotted the first constellation, and then head toward it until "Earth" shows up in your Planet/Moon Indicator.

**Orbiting and Landing—When Your Destination is Close** Each planet or moon has two landing areas, one on the bright side (facing the sun) and one on the dark side (away from the sun). To protect the secrecy of the test missions, the landing areas are changed from time to time. We can only tell you that you must be within 100,000 km of the planet or moon to be able to land; you may get landing clearance at any point within 100,000 km. This is where your interplanetary experience will be invaluable. The more you do it, the easier it will be.

Follow these general directions each time you want to land on any planet or moon. In this case, you want to land on Earth.

1. When you are within sight of a planet or moon, the Planet/Moon Finder will light up and you will see the name of the body and your distance from it in the Planet/Moon Indicator. If you have gotten this far, Earth should be in view. Center Earth in the Planet/Moon Finder and move toward it. (It might be best to do this at Low power.)
2. Move to within 100,000 km of the planet. You will hear a rhythmic sound to remind you that you are within 100,000 km. Use the brakes to keep your speed under control.

3. You must now locate a landing area on the planet or moon. If you are not already at Low power, shift to Low and begin to orbit the planet. The Planet/Moon Finder will flash and beep when you are above a landing area. The Finder will register the landing area only when you are less than 100,000 km from the planet or moon. Sometimes you may have to get closer before you can land.

   As you approach, be patient. Sometimes it takes a lot of orbiting before you find a landing area. Keep moving from side to side. Remember that only part of the planet may be visible. Don't forget to orbit the entire planet; you may get landing clearance from the dark side or the light side. Do not steer directly at a planet, especially when you get close. If you get too close, you will crash, which delays your mission. If this happens, you will see this message: “You crashed on Earth (or another planet), where you will spend one month recovering.” If you crash, you will be assessed a time penalty. Five minutes will be added to your time for that mission.

   There are two exceptions to this orbiting and landing procedure: Halley’s Comet and the sun. Because we are not at liberty to disclose the exact location of the training installation on Halley’s Comet, we don’t expect you to find a specific landing area there. You need only fly into the comet; P.L.A.N.E.T. will ensure that you return safely to the base. Landing on the sun is not ever advisable; it’s simply too hot.

4. When the Finder blinks and beeps to let you know it has located a landing area, press A on the keyboard to activate the Automatic Landing System. You will see a “Landing System Engaged” message on your Control Panel.
5. The ship will automatically land. You will see a message telling you which planet or moon you've landed on and indicating whether or not you successfully completed part of your mission. Your next destination will also be described. Again, the information you get about your next destination may be in the form of a clue . . . You've already been warned that you have to be more than good to qualify for The Halley Project.

6. Press any key to see a picture of the planet or moon you've landed on. In this case, you will see a picture of Earth.

7. Plan your course to your next stop. Then press B on the keyboard to blast off.
The Halley Project: Missions Chart

Use this chart to fill in mission destinations as you learn them. Once you figure out the clue, write in the name of the planet or moon that is your next destination. We need not remind you that this is confidential information. Please keep it tucked away safely in your dossier.

Sometimes more than one planet or moon can be the right answer. If, for example, you’re supposed to land on a moon of Saturn with no atmosphere and with a diameter of less than 1,500 km, you can go to either Tethys or Dione. Fill in either moon on your chart. Try different possibilities until you find the one that gives you the fastest time. Remember that the planets of the Solar System change positions as they orbit the sun, so a given combination may not always be the fastest.

Intelligence-Gathering Resources

There are many books about the different fields of astronomy and space exploration. Below are just a few suggestions, both non-fiction and fiction, for the beginning astronomer. To solve some of the clues in the program, you may also want to consult an encyclopedia.

**ASTRONOMY BOOKS**

**ASTRONOMY PUBLICATIONS**

*Astronomy*. 625 East St. Paul Avenue, P.O. Box 92788, Milwaukee, WI 53202. A magazine particularly suited to the amateur.

*Sky and Telescope*. Sky Publications, 49 Bay State Road, Cambridge, MA 02238. Excellent range of articles and information for beginners and more advanced astronomers.
**SPACE TRAVEL**

**SCIENCE FICTION**

Much popular science fiction involves visions of people in space, and there are many excellent books. Below are two authors who have excelled at combining science fiction with science fact.

Isaac Asimov is a prolific author of both fiction and non-fiction. He is well-known for both. Among his most popular science fiction works is the Foundation series.

Arthur C. Clarke is also admired for the scientific background he brings to his writing. Clarke is probably best known for authoring *2001: A Space Odyssey*.

Other popular science fiction authors include Ursula LeGuin, Frank Herbert, and Ray Bradbury.
After you complete your training missions, you may face a difficult readjustment period back on Earth. To remain in contact with activities in the Solar System, you may want to do some star-gazing as part of an on-going debriefing process.

All the stars you see in The Halley Project program and on the Simple Star Map included with the package are found along the ecliptic, a band of stars that includes the paths the sun, moon, and planets appear to take during the year. The portion of the ecliptic which can be seen on a given night depends on your location and the time of year.

The Ecliptic

Imagine that the Earth has an enormous ring or band wrapped around it—but very far away from it. This ring is the ecliptic, and it will usually look like a curved strip across the sky.
With some practice and a few helpful hints, you can locate in the sky some of the stars and constellations from The Halley Project. To find stars in the night sky, it is best to start with some familiar reference points. Earth’s moon, for example, can be used to pinpoint the ecliptic which, when you are familiar with the program, will contain many recognizable star patterns.

To get an idea of where the ecliptic is located at a given time, pick a two-week period starting one week before a full moon. The weather columns in newspapers usually contain a chart telling you when the moon’s phases occur. For each evening of that period, go outside at the same time and look at the moon’s location. You might want to keep a sketch showing your view of the sky and draw the moon’s position on it. After two weeks, you will see the moon’s positions form a curved band through the sky. That band shows the location of the ecliptic for your location and time of year. During the course of the year, the ecliptic moves up and down in the sky; in the summer it is higher, and in winter it is down lower, near the horizon.

Next, look for a simple but familiar pattern in the stars of the ecliptic. The tight cluster of stars in Taurus (called the Pleiades), the twin stars of Gemini, or the three bright stars of Scorpio, for example, are fairly distinctive combinations of stars. Once you find one constellation, you can follow the ecliptic to pinpoint others.

Once you become familiar with some constellations and get your bearings in the night sky, you can become a real stargazer. A variety of “star finder” devices and simple telescopes are available to aid your stargazing.
TOP SECRET
Coded transmission from P.L.A.N.E.T. follows.

**Classified Code Red.**

Tune to secure frequency ALPHA BRAVO NINER CHARLEY SEVEN SEVEN SEVEN STROKE SEVEN DELTA NINER.

P.L.A.N.E.T. HQ To Star Pilot
RE: The Halley Project

Congratulations.
You have been chosen from the best pilots in the Solar System to compete for a spot on The Halley Project team.

Your record indicates that you are an intelligent, resourceful, and skilled pilot, but those things are merely the beginning for a Halley pilot. To take part in The Halley Project you also need courage, tenacity, and a detailed knowledge of the Solar System. Unless you possess all these qualities, back down now.

**WARNING:** Reading this dossier will be interpreted as acceptance of this assignment. If you do not wish to take part, DO NOT CONTINUE.
To participate in The Halley Project, you must complete 10 missions in our Solar System. Each will be more difficult than the last. You will be required to visit various planetary and lunar bodies. You will be told your goals in flight. As you complete each leg of a mission, your next destination will be transmitted to you. Sometimes you will be told exactly where to go; other times the information will be little more than cryptic clues.

To aid your navigation you will have the P.L.A.N.E.T. SSM (Simple Star Map) showing the zodiacal constellations (it isn't much, but it's better than nothing!) and whatever resources you bring with you.

All trainees will pilot the Mark Five Hyperjump Trainer (air conditioning, cruise control, and tape player optional). Your ship is equipped with the latest hyperspace drive and long-range radar. You will find complete technical operating instructions in the MTRG (Mission Technical Reference Guide) in your dossier.

Since different ships have different computers installed, please check the FIRC (Flight Instructions Reference Card) for detailed launch instructions for your particular vessel.

Should you have difficulty with any of the mission objectives, there will be two directions you can take. The first is to give up and go home and forget about The Halley Project—we sincerely hope you don't seriously consider this option; after all, P.L.A.N.E.T. selected you specially. Second, and more highly recommended, is to find your nearest interplanetary library (where BOOKS are kept—books are an ancient form of mass storage) and ask for information about the Solar System.

If you manage to complete all 10 missions you will have the satisfaction of knowing that you are truly one of the best pilots in the Solar System. You will also have qualified for The Halley Project—the ultimate and most difficult mission of all. Details of this mission will only be given to you when you have completed the tenth mission and therefore achieved the rank of Starbird. Once you have qualified for The Halley Project, which those of us here at HQ consider THE FINAL CHALLENGE, fill out and send in the RFC (Registration For Certification) found in the enclosed dossier. Special instructions for The Halley Project will be sent directly to your ship at the address you supply. The RFC must arrive at P.L.A.N.E.T. Headquarters by December 31, 1985, if you want P.L.A.N.E.T. to compare your performance with that of other pilots.

Good luck, Star Pilot—you're going to need it.

Remember the Space Corps Motto: Keep your feet on the ground and reach for the stars!

P.L.A.N.E.T. OUT
The design of The Halley Project was quite a challenge. Our goal was to create an exciting product based on an accurate model of the Solar System. Certain minor compromises had to be made to enhance the speed and play of the program. The expanse of the Solar System is immense, and we did not want people to get lost among the stars. Microcomputer technology also presented some limitations.

While the constellations of the ecliptic are accurate, not all the stars one might see in space are displayed in the program. The Halley Project includes stars of sixth magnitude or brighter, similar to what is found on many star maps. You will notice, however, that the computer did not allow us to distinguish among the stars' varied brightnesses. Computer limitations also did not permit us to include all the moons of Jupiter and Saturn in the program. Five of Jupiter's known moons and five of Saturn's known moons appear in The Halley Project.

In the real Solar System, the planets look different from the way they appear in The Halley Project. Real planets are different colors, and some have rings. Also, some of the planets' orbits extend outside the plane of the ecliptic. We have flattened those orbits so that all the planets would travel in the same plane. However, the relative size of the bodies, the distances between them, and the speeds of lunar orbits are accurate.

One other area where we had to make adjustments is in your spaceship. The brakes, of course, are not realistic, and neither is the rate at which you are able to accelerate. Finally, Hyperspace does not really exist. It is impossible to travel at the speed of light, and certainly not at many times faster than that. Without Hyperspace, however, it would have literally taken years to complete some of the missions in the program.

We hope you agree that these minor compromises help to make The Halley Project a fun, challenging experience. We also hope you agree that despite these changes, The Halley Project offers an opportunity to understand the basic relationships between the planets, moons, and some of the constellations in our Solar System.
